

A to Z

Water Movement in Soils

Randy Miles

**2019 Northeast Onsite Wastewater
Short Course**

April 3, 2019

Ideal Soil for Dispersal and Treatment of Wastewater

- Deep
- Permeable
- Well Drained (Well Aerated)
- Loamy
- Ample Area

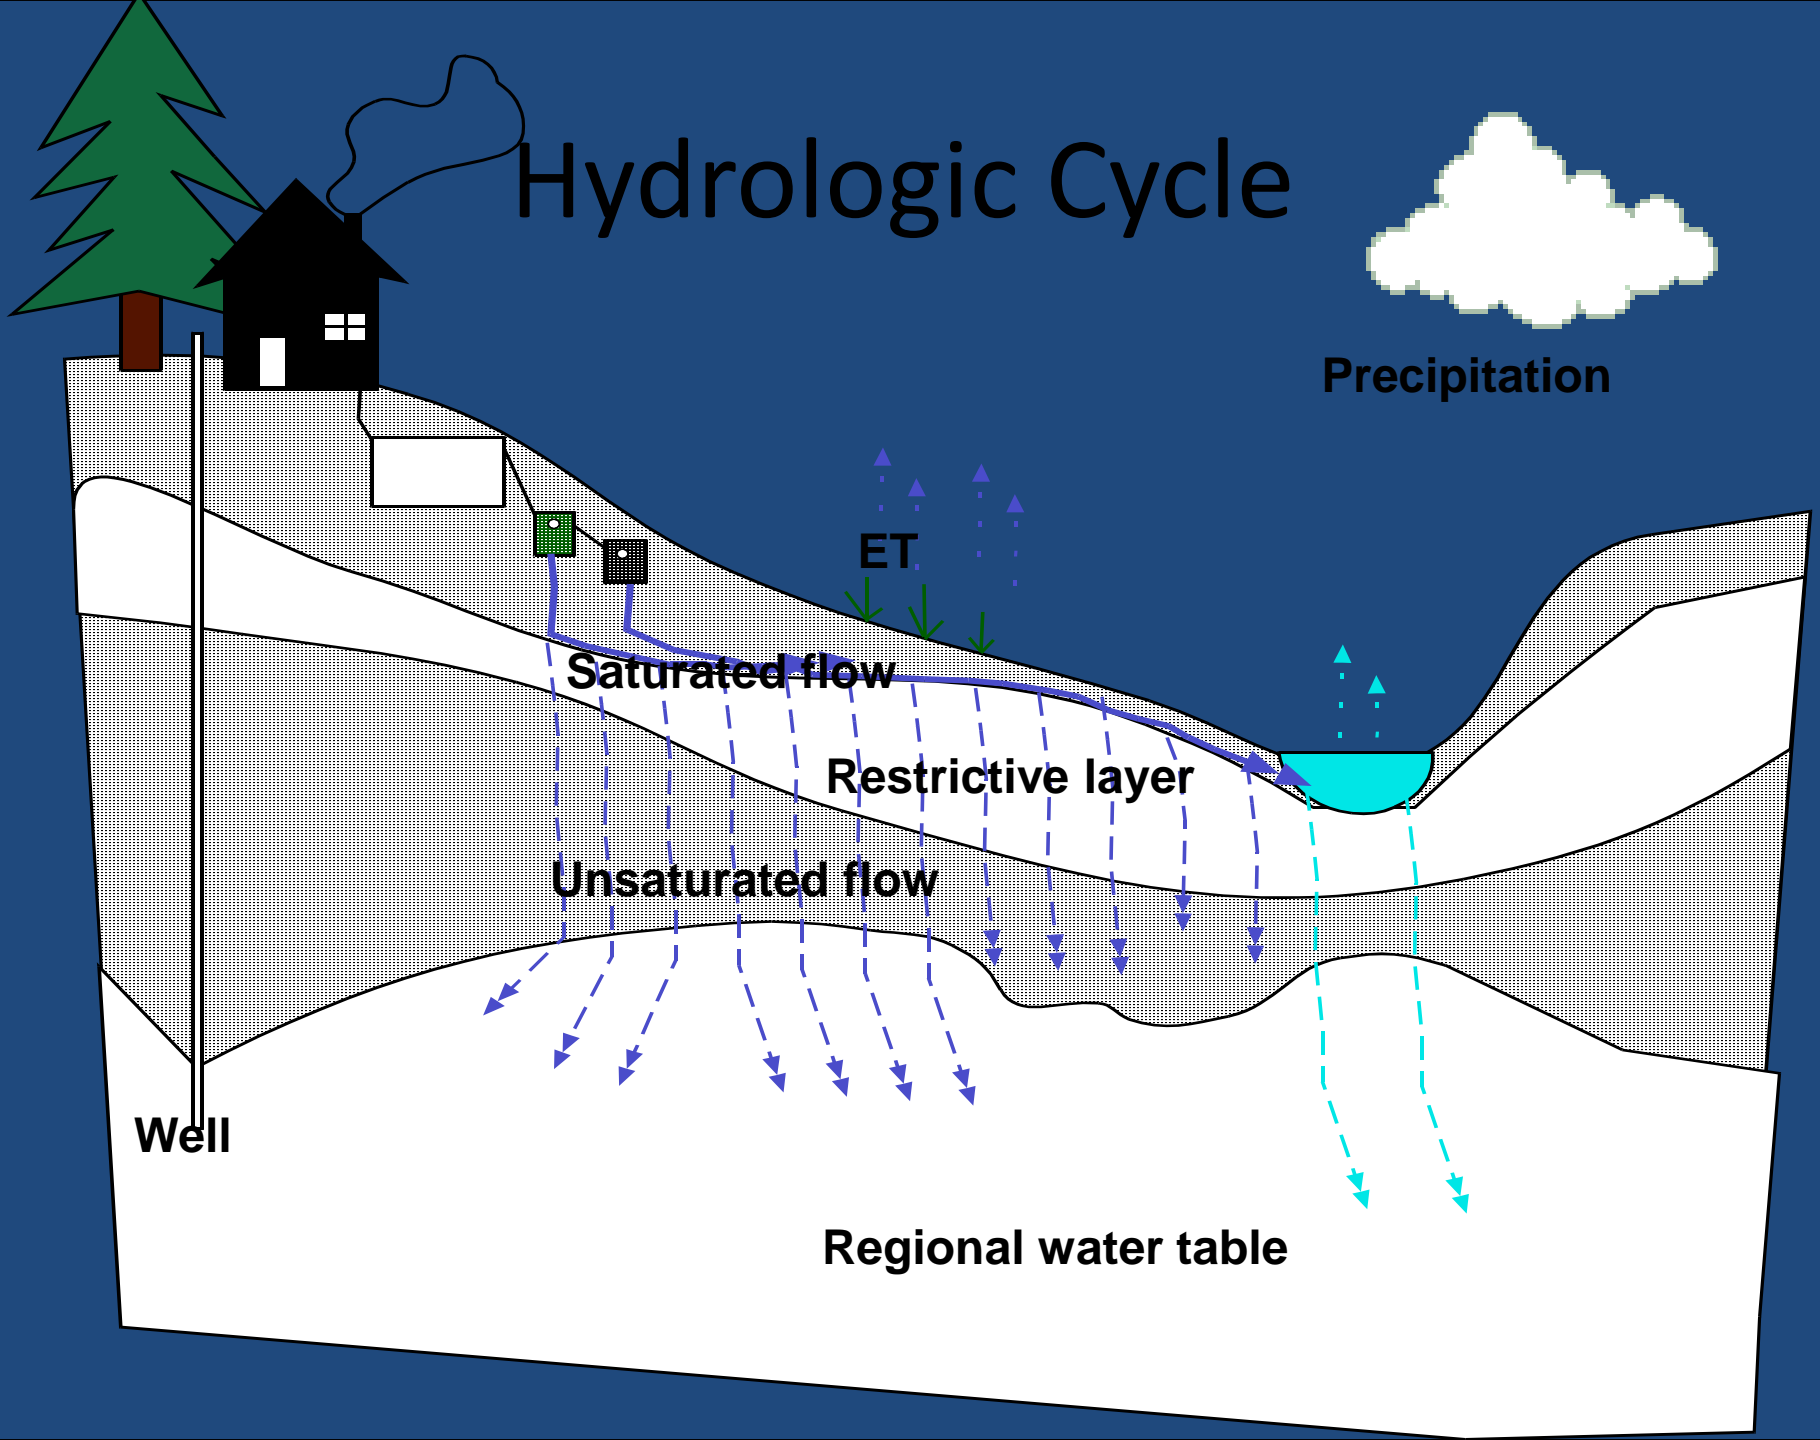

Aerobic zone

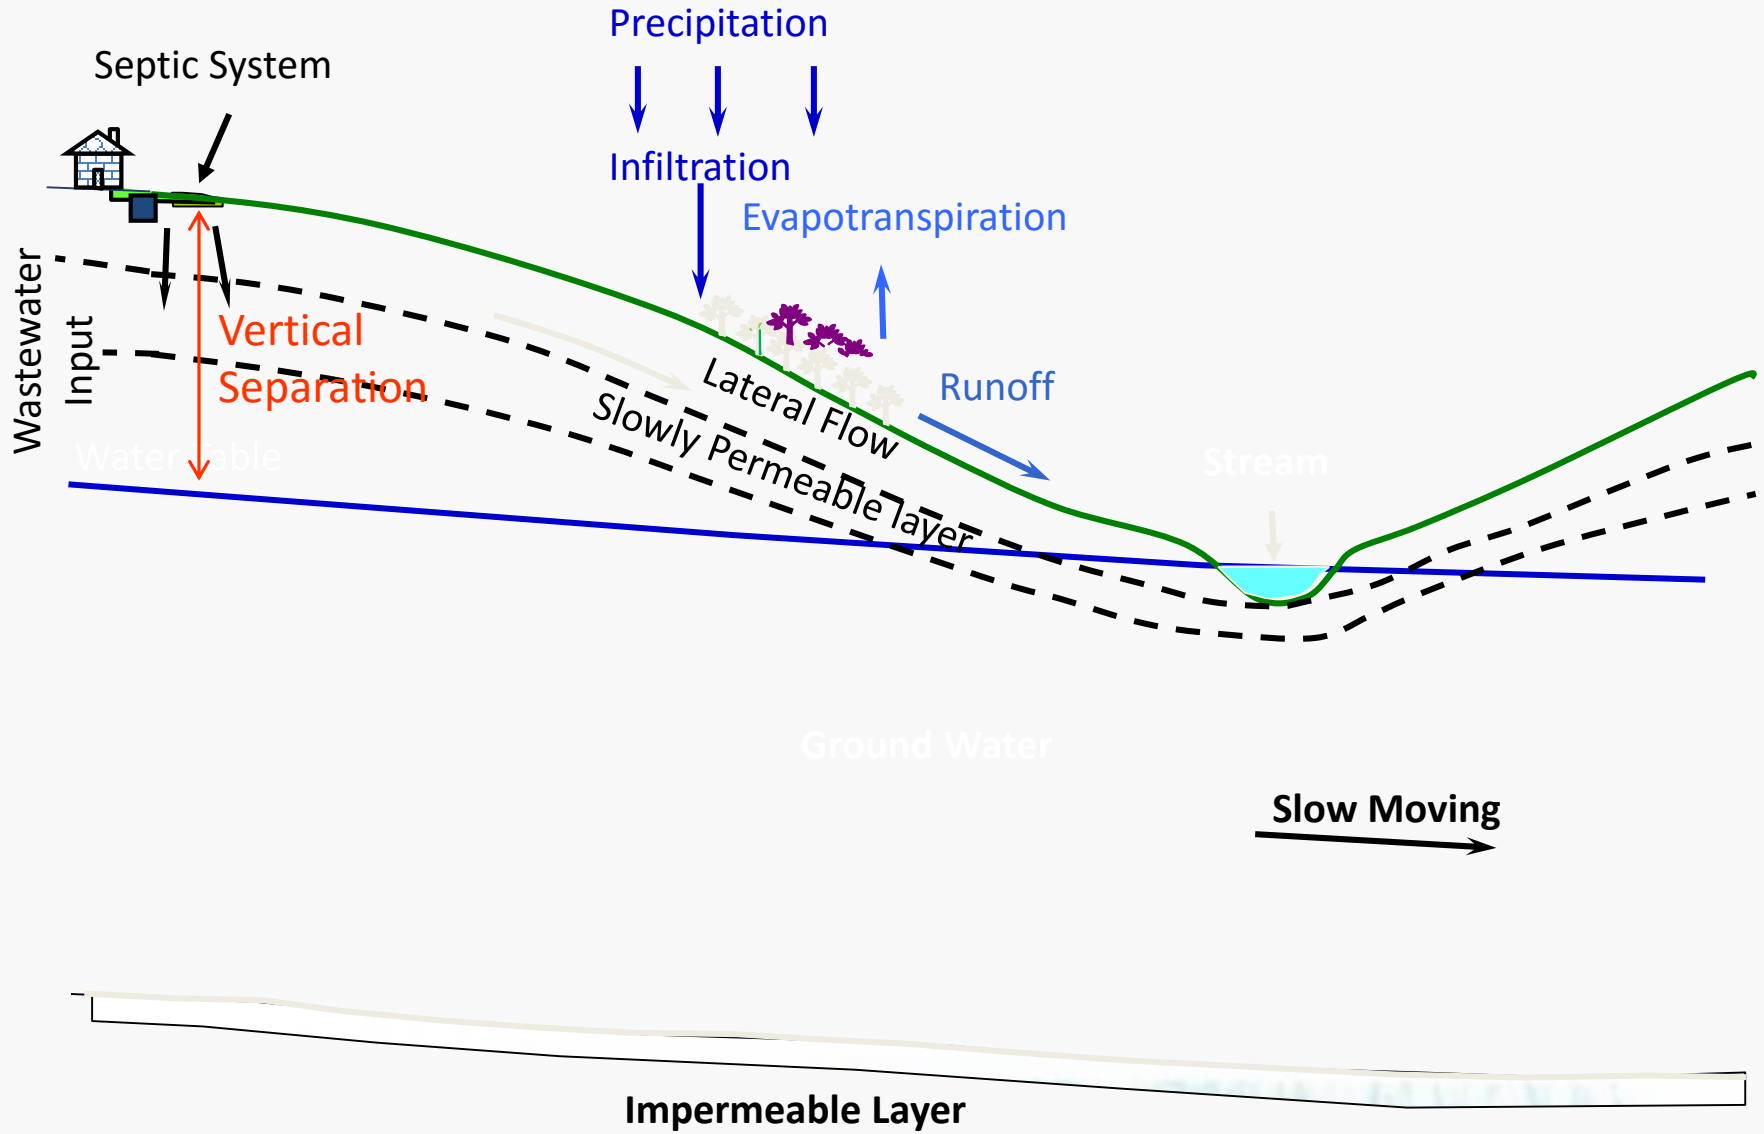

Many Soils Possess Drainage Restrictions

- Redoximorphic Features
- Mottles
- Landscape Position
- Location within the Watershed

Hydrologic Cycle

Hydrologic Cycle

- The best location for an absorption field on the site is where flow will diverge (note the red flow lines). Areas where water naturally converges (note blue flow lines) should be avoided.

Water Tables

- Apparent: Ground Water Table
- Perched: Laying on top of (“perched”) a horizon or zone which is not saturated. With the lack of vertical movement, there may be a significant lateral flow vector.

Apparent Water Table

Perched Water Table

Slope Considerations

To Better Understand Management of Water One Must Understand how Water Moves in Soils

- Saturated Flow: All pores are filled with water; gravity moves much of the water
- Unsaturated Flow: Movement by capillarity or matric potential; the attraction of water to soil surfaces and pore walls.
- In unsaturated flow that material with the greatest surface area has the largest affinity to water.

In Other Words:

- Sands and Gravels do NOT attract or pull water when surrounded or embedded within soil materials!
- Sands and Gravels do NOT suck

In other words, gravel at the bottom of a vented flower pot will NOT drain the pot!

Therefore, gravel around a drain tile below soil fill will NOT drain the soil!

Unsaturated vs. Saturated flow

Unsaturated

- Pores: Air available
- Slower:
Next to particles: in small pores
- Aerobic

Saturated

- Pores: Volume filled with water
- Faster:
In large pores
- Non aerobic

Saturated Conditions

***Pores are
filled with
water***

What is Saturation

- A horizon is saturated when the soil water pressure is zero or positive

In layman's terms

- Water flows from the soil into a hole

***Auger hole in soil is filled
with air just after digging***

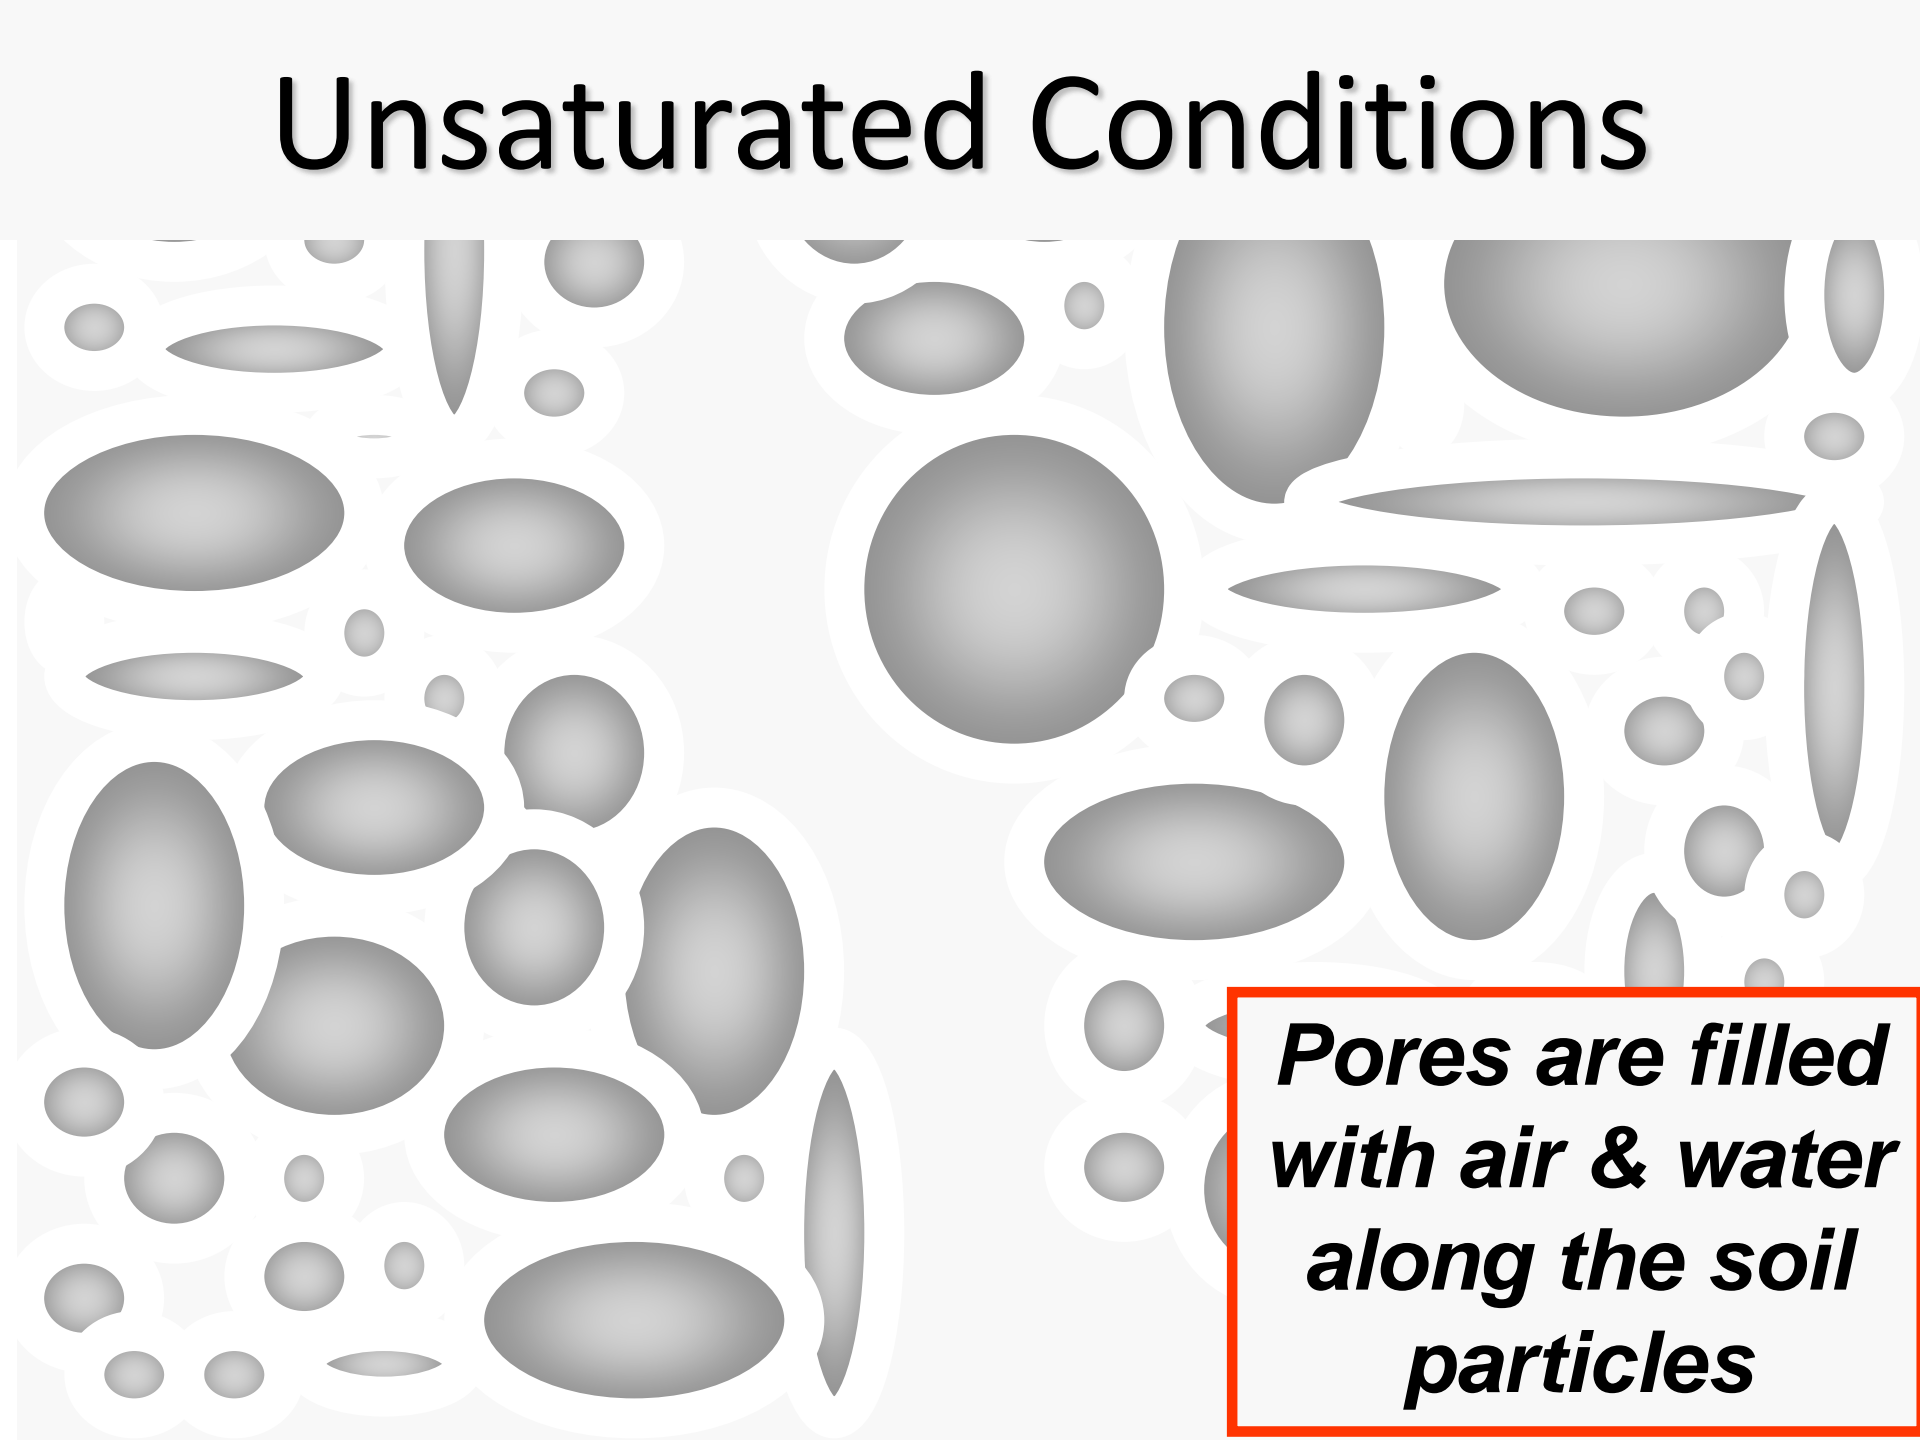

Water table

Air

Free water is not under a suction, and flows in response to gravity.

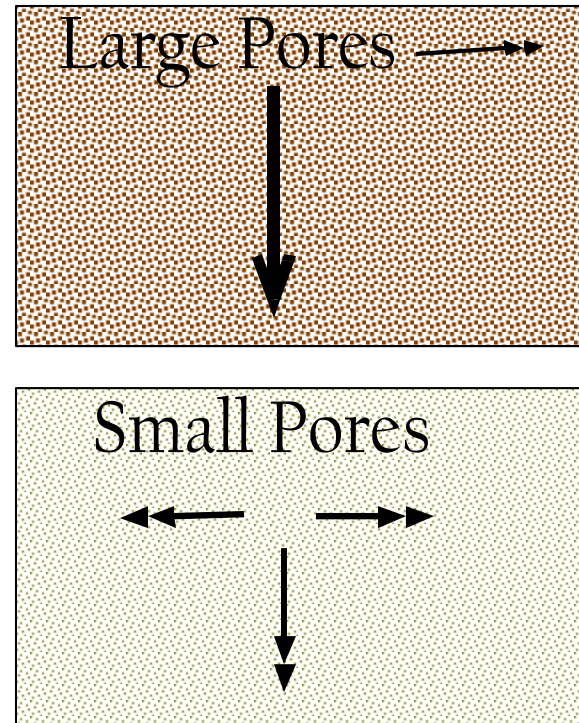

Unsaturated Conditions

The diagram illustrates soil pores under unsaturated conditions. It features a light gray background with a network of white, irregular shapes representing soil particles. The spaces between these particles are filled with dark gray, representing air and water. The distribution of these dark gray areas is uneven, with some larger, more rounded shapes and many smaller, more elongated or irregular shapes, indicating a heterogeneous pore structure. A red-bordered box in the bottom right corner contains text describing the pore contents.

***Pores are filled
with air & water
along the soil
particles***

Pore size & unsaturated flow

- Large pores water will moved predominantly by gravity
- Small pores water will move in all directions better & further

***Auger hole in soil is filled
with air just after digging***

Wetting Front Stacks Up Above Boundary

Water Breaks Course Sand Boundary

Trench Flow Examples

**1.
Effluent
flows
into pipe**

**2.
Effluent
flows out
of pipe
and into
gravel**

**4.
Biomat
begins to
form**

**3.
Effluent
begins to
pond and
flows
across
soil
interface.**

5. Effluent flows into soil

Unsaturated Flow**

Surface Water Management

Use of Swales, Berms, Surface
Diversions, Terraces, etc.

Poor storm water management

Swale for Surface Water Management

Grass-lined swale should be a minimum one foot wide at bottom and one foot deep with a maximum slope of 5 percent.

Diversion berms and swales

- Required?
- Present and effective?

System

Swale

Exit of surface swale below system

Berm

HYDROLOGY OF A SEPTIC SYSTEM

Infiltration from
Trenches

Vertical Movement
through the
Unsaturated Zone

Lateral Movement
in the Saturated Zone

How does slope influence the hydrology of a septic system?

Flow pattern in sub-surface trench

Capillary Fringe

- Unsaturated zone above the water table
- Water held in this zone by tension (matric potential, adhesive and cohesive forces)
- This zone is generally not important to us, and is difficult to measure

Strip Drain: Note Gravel Completely to the Surface!!!

Place strip drain into 4 inch wide trench and backfill with pea gravel. Slope strip drains to a tightline.

Based on the Principles of Water Movement under Saturated and Unsaturated Conditions: A Curtain Drain Should:

- Be dug into the restrictive layer to serve as a trough.
- Must be diverted around the soil treatment field
- Must have an outlet in which the water does not intrude on the soil treatment field.
- Have trench filled with coarse aggregate material or other suitable material to the SOIL SURFACE!

Remember:

- Sands and Gravels do NOT attract or pull water when surrounded or embedded within soil materials!
- Sands and Gravels do NOT suck

In other words, gravel at the bottom of a vented flower pot will NOT drain the pot!

Therefore, gravel around a drain tile below soil fill will NOT drain the soil!

Based on the Principles of Water Movement
under Saturated and Unsaturated
Conditions: A Curtain Drain Should:
(continued)

- Have a clear path for outlet discharge.
- Have rodent guard or screen over the open pipe.
- Not have soil over the coarse aggregate or similar material so that surface runoff can be collected and the system may breathe.

Potential Curtain Drain Site

Curtain Drain Placed at Site

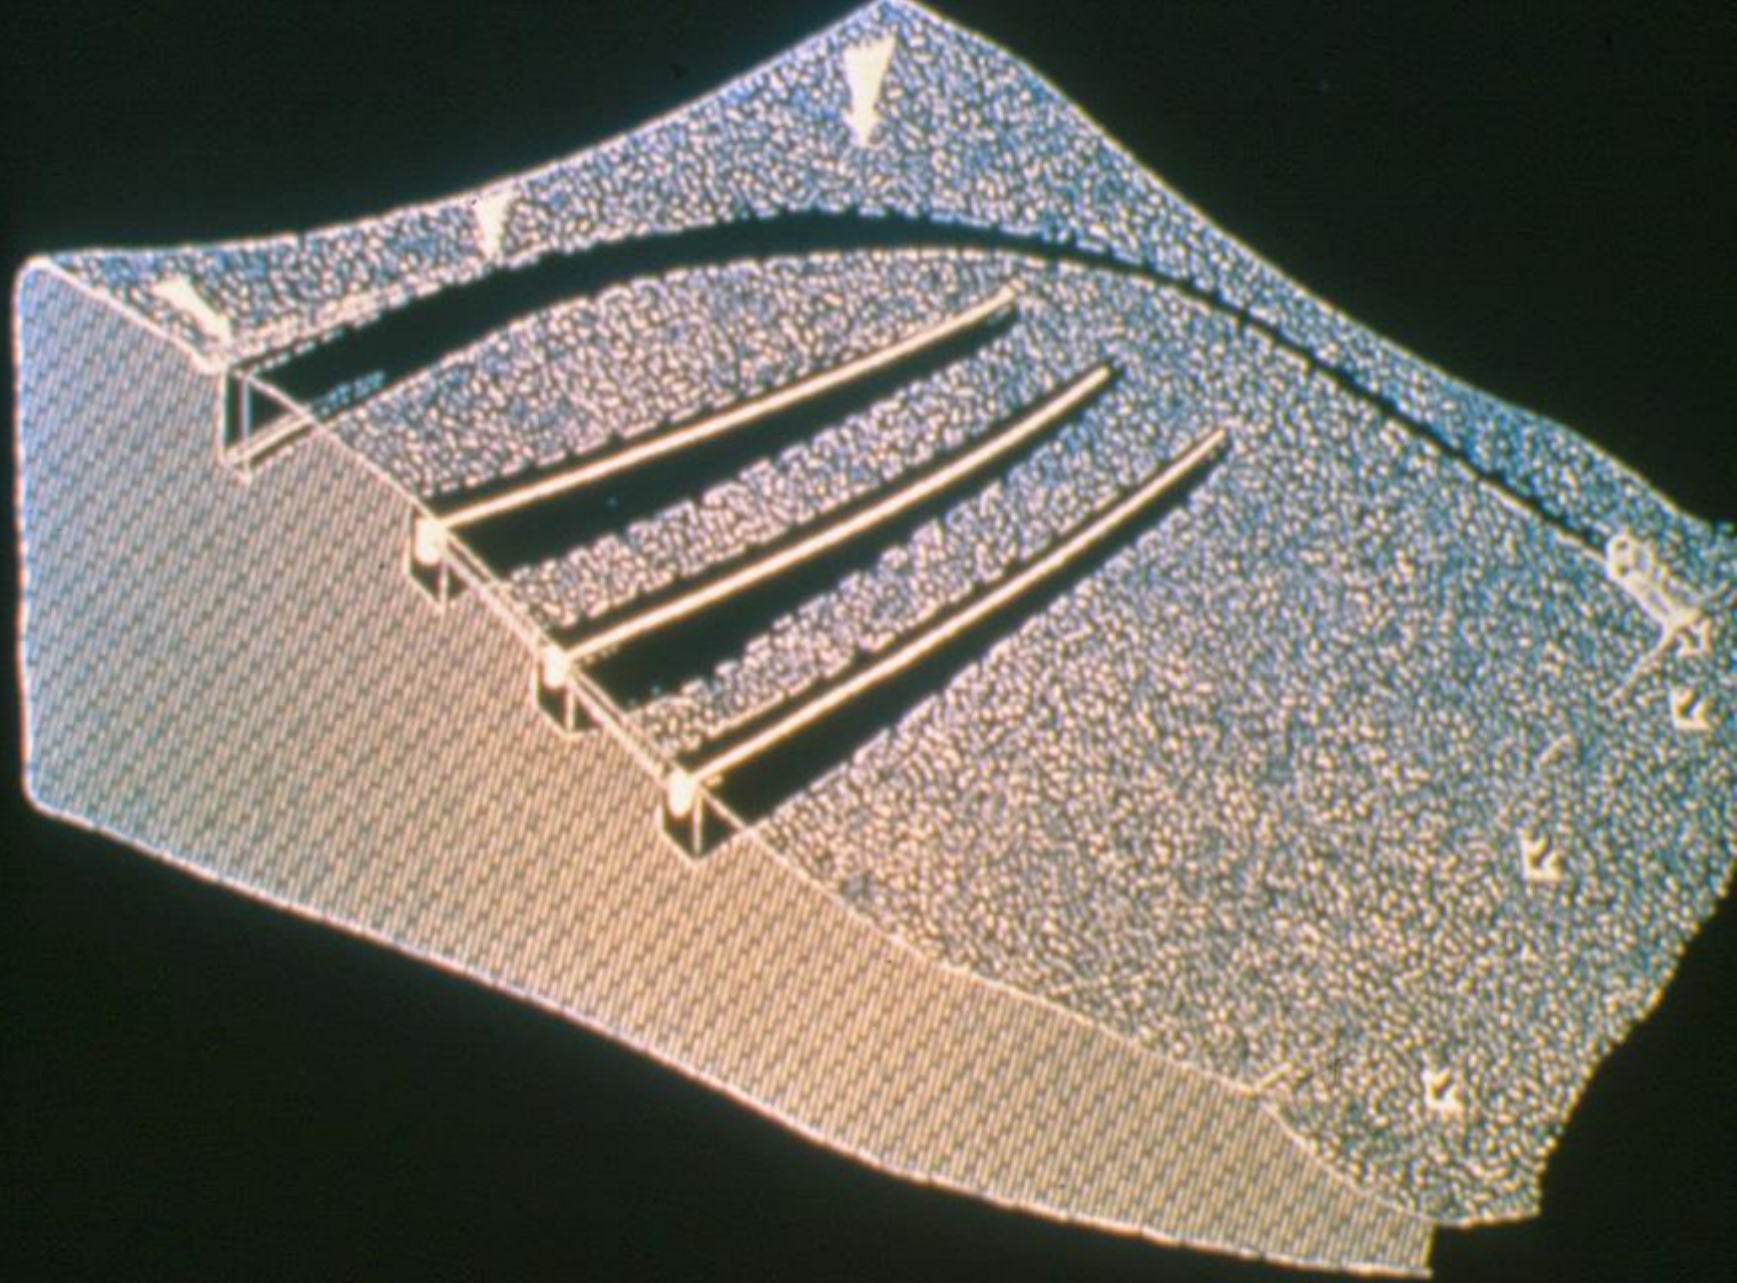

Curtain Drain

Curtain Drain

Limiting Layer

Proper Outlet for Curtain Drain

Outlet

A proper outlet must.

- be clear and free flowing.
- exit topographically below the bottom of the deepest trench

Outlet open to drainage

- 
- A photograph showing a concrete drainage outlet pipe in a trench. The pipe is open and surrounded by snow and vegetation. The pipe is made of concrete and has a circular opening. The trench is dug into the ground, and the pipe is positioned at the bottom. The surrounding area is covered with snow and some green plants are visible. The pipe is connected to a larger concrete structure above it.
- Clear and free flowing
 - Exit topographically below the bottom of the deepest trench

Rodent guard on outlet

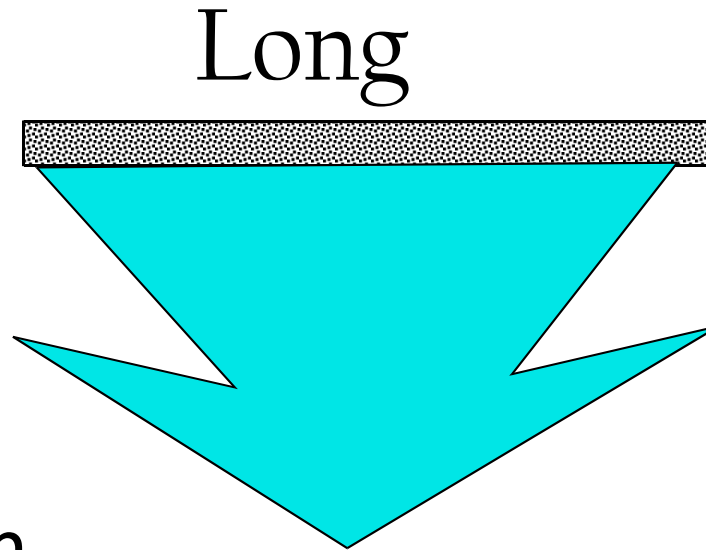

A well maintained surface water diversion ditch

System Geometry

- Influences:
- Longer area
 - Smaller loading
- Shorter length
 - Greater down slope impact

Direction of Ground water Flow

Slope Considerations

Critical considerations for drainage

- Conductivity of underlying material
- Zone of influence – draw down
- Depth of ditch/outlet
- Outlet for drain
- Long-term maintenance of water lowering system
- Topographic position

Curtain Drain
